## 1 Overview

Using VMware, we have created a pre-built virtual machine (VM) image for UbuntuLinux (version 11.04). This VM can be used for all our SEED labs that are based on Linux. In this document, we describe the configuration of this VM, and give an overview of all the software tools that we have installed. The VM is available online from our SEED web page.

Updating the VM is quite time-consuming, because not only do we need to update the VM image, we have to make sure that all our labs are consistent with the newly built VM. Therefore, we only plan to update our VM image once every two years, and of course update all our labs once the VM is changed.

## 2 VM Configurations

### 2.1 Configuration of the VM

The main configuration of this VM is summarized in the following. If you are using VMware Workstation, you can adjust the configuration according to the resources of your host machine (e.g., you can assign more memory to this VM if your host machine has enough memory):

- Operating system: Ubuntu 11.04 with the Linux kernel v2.6.38.
- Memory: 512M RAM.
- Disk space: Maximum 20G disk space.

We have created two accounts in the VM. The usernames and passwords are listed in the following:

1. User ID: `root`, Password: `seedubuntu`.

**Note:** Ubuntu does not allow `root` to login directly from the login window. You have to login as a normal user, and then use the command `su` to login to the `root` account.

2. User ID: `seed`, Password: `dees`

### 2.2 Network setup

Currently the “Network connection” is set to “NAT”, i.e., your VM is put in a private network, which uses your host machine as the router. The VMs in such a setting can connect to the Internet via the NAT mechanism, and they are not visible to the outside (their IP addresses are not routable from the outside, e.g., many use 192.168/16 prefix). This setting is sufficient for most of our SEED labs.

If you want your VMs to be visible to the outside (e.g., you want to host a HTTP server in a VM, and you want to access it through the Internet), then, you have to set the “Network connection” to “Bridged”, or you can use the port forwarding mechanism (see our “VPN lab” for detailed instructions).

## 3 Libraries and Software

### 3.1 Libraries and Applications Installed

Besides the packages coming with the Ubuntu 11.04 installation, the following libraries and applications are additionally installed using the `"apt-get install"` command.

```
libnet1, libnet1-dev, libpcat-dev, libpcap-dev, libattr1-dev,  
vim, apache2, php5, libapache2-mod-php5, mysql-server,  
wireshark, bind9, nmap, netwox/netwag, openjdk-6-jdk, snort, xpdf,  
vsftpd, telnetd, zsh,
```

The `libcap 2.21` and `libcap1.2.0` have been compiled and installed from the source downloaded from the Internet.

### 3.2 Softwares configuration

**Netlib/netwox/netwag.** `Netwox` is a network toolbox; `netwag` is a GUI of `netwox`. They can be found in `/usr/bin/`. The ICMP spoofing bug of `netwox` has been fixed. It should be noted that running `netwox/netwag` requires the root privilege.

**Wireshark.** `Wireshark` is a network protocol analyzer for Unix and Windows. It is located in `/usr/bin/`. `Wireshark` requires the root privilege to run.

**Nmap.** `Nmap` is a free security scanner for network exploration and hacking. It is located in `/usr/bin/`. Some functions of `nmap` require root privilege.

**Firefox extensions.** `Firefox` is installed by default in Ubuntu 11.04. We have installed some useful extensions, including `LiveHTTPHeader`s, `Tamper Data`, and `Firebug`. They can be launched in the "Tools" menu in `Firefox`.

**Collabtive web application.** For some labs, especially those related to web security, we need a non-trivial web application. For that purpose, we have installed the `Collabtive` web application. Several versions of `Collabtive` are installed; most of them were modified from the original version to introduce different vulnerabilities.

It should be noted that to access `Collabtive`, the `apache2` http server and the MySQL database server must be running.

**Java.** We have installed `openjdk-6-jdk`, the OpenJDK Development Kit (JDK) 6 for Java. The commands `javac` and `java` are available to compile and run java source code.

## 4 Pre-Installed Servers

Some of the SEED labs may need additional services that are not installed or enabled in the standard Ubuntu distribution. We have included them in our pre-built VM. Note: You need root privilege to start a server.

## 4.1 The MySQL Server

The database server MySQL is installed. It can be started by running `"service mysql start"`. Currently, there are two accounts in the MySQL server. The usernames and passwords are listed below.

1. root : seedubuntu
2. apache : apache (web applications use this account to connect to the mysql server)

You can access the MySQL database server by running the client-side application `/usr/bin/mysql`. The following is a simple demo on how to use `mysql`.

```
$ mysql -u root -pseedubuntu

mysql> show databases;

mysql> use db_name;

mysql> show tables;

mysql> select username,user_email from table_name;

mysql> quit
```

## 4.2 The Apache2 Http Server

The `apache2` http server was installed using `"apt-get install"`. It can be started by issuing the `"service apache2 start"` command. The `apache2` server is configured to listen on both 80 and 8080 ports. All the web pages hosted by the server can be located under the `/var/www/` directory.

For each SEED lab that uses the `apache2` http server, we have created one or several URLs. Basically, in the pre-built VM image, we use Apache server to host all the web sites used in the lab. The name-based virtual hosting feature in Apache could be used to host several web sites (or URLs) on the same machine. A configuration file named `default` in the directory `"/etc/apache2/sites-available"` contains the necessary directives for the configuration. The following is a list of URLs that we have pre-configured; their corresponding directories are also listed:

<code>www.csrfcollabactive.com</code>	<code>/var/www/CSRF/Collabactive/</code>
<code>www.csrfcollabattacker.com</code>	<code>/var/www/CSRF/Attacker/</code>
<code>www.sqlcollabactive.com</code>	<code>/var/www/SQL/Collabactive/</code>
<code>www.xsscollabactive.com</code>	<code>/var/www/XSS/Collabactive/</code>
<code>www.soplab.com</code>	<code>/var/www/SOP/</code>
<code>www.soplabattacker.com</code>	<code>/var/www/SOP/attacker/</code>
<code>www.soplabcollabactive.com</code>	<code>/var/www/SOP/Collabactive/</code>
<code>www.soplab.com:8080</code>	<code>/var/www/SOP/</code>

**Configuring DNS.** The above URL is only accessible from inside of the virtual machine, because we have modified the `/etc/hosts` file to map each domain name to the virtual machine's local IP address (127.0.0.1). You may map any domain name to a particular IP address using the `/etc/hosts`. For

example you can map `http://www.example.com` to the local IP address by appending the following entry to `/etc/hosts` file:

```
127.0.0.1      www.example.com
```

Therefore, if your web server and browser are running on two different machines, you need to modify the `/etc/hosts` file on the browser's machine accordingly to map the target domain name to the web server's IP address.

### 4.3 Other Servers

**DNS server** The DNS server `bind9` is installed. It can be started by running `"service bind9 start"`. The configuration files are under `/etc/bind/`.

**Ftp server.** The `vsftpd` (very secure ftp daemon) server is installed. It can be started by running `"service vsftpd start"`.

**Telnet server.** The `telnetd` server is installed. It can be started by running `"service openssh-inetd start"`.

## 5 Miscellaneous Configuration

**Time zone** Currently the time zone is set to be New York, adjust that to the time zone of your location.

**Display resolution** The current Display resolution is 1024\*768. You can change it at "System → Preferences → Monitor".

## 6 Configure Your VM securely

### 6.1 Change the password

For the sake of security and your own convenience, we suggest that you change the account password. To change the Ubuntu's account password. You need to login as root and issue the `"passwd username"` command. To change MySQL's root password. You can do it as following:

```
$ mysql -u root -pseedubuntu
```

Once in the prompt do this:

```
mysql> update user set User='NewRootName', Password='NewPassword'
      where user='root';
mysql> flush privileges;
```

## 6.2 Configure automatically start service

It's more convenient to start some commonly used service automatically during the system boot up, although most people do not want to start some server that they do not use.

Currently, most of the service (except the Apache and MySQL servers) we need for SEED labs are configured not to start automatically. You can use `chkconfig` to get the current configuration. You can also use `chkconfig` to modify the configuration. For example, to start the server XYZ automatically during the system bootup, run "`chkconfig XYZ on`".

## 7 Note

### 7.1 Don't install VMware Tool on the Ubuntu

Though it is highly recommended to install VMware Tool in a virtual machine, VMware Tool of VMware may cause a mouse-focus problem. We suggest you not to install VMware Tool on the pre-built Ubuntu VM. If you do want to give it a try, please make a snapshot of your VM image, so that you can recover to the previous state in case it might go wrong.

### 7.2 Run the VM in proper version of VMWare

This VM is build on VMware Workstation v6.5.7. To use this VM, you should open SEEDUbuntu11.04.vmx in VMware Workstation v6.5.3(or newer version) or VMware Player. It's recommended that your host machine which VMware runs on should have at least 2G RAM, and 20G free disk space.

**Note for Macintosh Users** The pre-configured virtual machine is not compatible with VMware Fusion 1.x. If you are using VMware Fusion 1.x, then you may download a free upgrade to VMware fusion 2.5 from the following web site <http://www.vmware.com/download/fusion/>. Our pre-configured virtual machine has been tested on VMware Fusion 2.04 and 2.05.
